CampusCue App Business Plan

A multimodal campus task assistant

Mobile Intelligent Applications | Phase One | Group 16 | 19 October 2026

Team leader: 何嘉俊. Team members: 王舜祺, 陈实 and 李文豪.

1 App overview

CampusCue is a proposed mobile application for students who receive assignment requirements and campus notices across screenshots, classroom recordings, documents and short videos. It turns selected materials into task drafts with deadlines, submission requirements and source references. Students review those drafts before enabling reminders.

The initial focus is coursework deadlines and submission requirements in one university cohort. We aim to reduce the effort of retyping requirements and make uncertain or conflicting instructions visible. General lecture summarisation, answer generation and a campus social network are outside the initial scope.

Unique selling proposition

The proposed differentiator is a coursework task review flow: combine sources for one assignment, link each extracted requirement to its evidence, highlight deadline conflicts and retain confirmed reminders. Existing products already support document and media processing [2-4]. We will therefore evaluate the complete workflow, including review and scheduling, against those alternatives.

Illustrative user journey

A student imports an assignment PDF and an authorised classroom recording. The PDF requests a Friday submission, while the recording appears to move it to Monday. CampusCue proposes one assignment with both source references and a conflict flag. The student checks the teacher's latest instruction and confirms a deadline. The app then saves the task and schedules the chosen reminders. This is a design scenario, not a completed product demonstration.

Stage	Proposed scope
First development milestone	Text, JPG/PNG, text based PDF, DOCX and short recorded audio; extraction, source review, explicit date conflicts within a user selected assignment and local reminders.
Second development milestone	Short MP4 video with audio and selected frames; scanned PDF support; cross source duplicate and conflict suggestions.
Later exploration	Long recordings, shared group tasks and more file formats, only after initial accuracy and retention tests.

The phase one deliverable is this business plan and project repository documentation. Product features and performance in this plan are proposals. No functioning application or completed user study is claimed.

2 Target users and market analysis

Primary users are undergraduate students managing several courses whose requirements arrive through different channels. The proposed first recruitment group is the team's own course cohort because users and task examples are accessible. Secondary users are student group leaders who consolidate requirements for their teams.

Evidence and limits

A China Youth Daily and China Youth Campus Media survey published on 23 January 2026 collected 2,014 valid university student responses. In that sample, 53.14% wanted classification tags on campus walls and 47.06% wanted outdated information removed [1]. This supports investigating information organisation. It does not establish assignment omission rates, willingness to pay or demand for CampusCue. Local interviews and trials are still required.

Provisional user personas

Persona A is an undergraduate managing weekly assignments across several courses. Their current method is saving group screenshots and manually copying dates into a phone calendar. The trigger is receiving a new assignment file. Their goals are to capture all deliverables quickly and revisit the exact source when unsure. Adoption depends on review taking less effort than manual entry.

Persona B is a student group leader consolidating revised requirements for teammates. The trigger is a correction announced in class after an earlier file was shared. Their goal is to verify which deadline applies and keep the supporting evidence together. They need control over corrections and clear separation of teacher requirements from personal preparation dates. Both personas are hypotheses for recruitment, not descriptions of interviewed participants.

Alternatives and competitive position

Alternative	Verified strength	CampusCue hypothesis to test
Manual notes and calendar	A practical baseline with direct user control.	Less retyping without making confirmation burdensome.
Dida365 [2]	Official help documents voice task entry and recognition of dates and reminder times.	Value in extracting several requirements from course materials and retaining their evidence.
Feishu Minutes [3]	Official help documents AI meeting summaries, action items and transcripts.	A focused coursework experience across notices, assignment files and recordings.
Kimi [4]	Official help lists PDF, Word, images and video among supported formats.	A repeatable review and reminder workflow with explicit handling of uncertain requirements.
Prior course AITODO [6]	Its README describes goal decomposition and conversational task management.	A focus on extracting requirements from coursework source materials and reviewing revisions.

This is a comparison of documented capabilities, not a claim that alternatives lack any unlisted feature. We will test equivalent tasks against manual entry and one available AI alternative before claiming superior results.

Initial market sizing

We will begin with one accessible cohort rather than claim a national market. The planning funnel is 50 consenting invitations, 20 trial sign ups and 12 activated users. These are experiment targets, not observed demand. Reachable cohort size, frequent need and paid conversion remain unknown, so no revenue forecast or national market estimate is asserted.

3 Product scope and AI feasibility

Input	Proposed processing	Evidence shown to the user
Photos and screenshots	OCR or a vision model extracts text and layout.	Original image and relevant text region.
PDF and Word	Parse text and structure; use OCR for scanned pages in a later milestone.	PDF page; DOCX heading or paragraph, since page layout can change.
Classroom audio	Speech recognition followed by task extraction.	Transcript excerpt and recording timestamp.
Short video	Analyse audio plus selected frames containing slides or instructions.	Timestamp, transcript and relevant frame. Audio only processing is not full visual understanding.

A common task representation

Each draft stores a title, course, required deliverable, submission channel, raw deadline wording, interpreted date and time, source references and review status. Missing fields stay empty. Imported documents are source material, not executable instructions for the application.

The pipeline accepts a file, extracts its content, asks an AI model for structured task candidates, validates the fields and presents the candidates for review. Calendar storage and reminders follow user confirmation. A proposed Android client uses a backend for model calls and document processing so provider credentials are not embedded in the app. The course permits existing models. The team will select services after checking budget, data handling and implementation skills.

Reliability as a product feature

Relative dates require the date of the original notice or recording, not just the upload date. A phrase such as "before October 21" must not silently become October 21 at 23:59. Suggested personal work dates remain separate from teacher deadlines. Conflicting sources are shown together, and an automatically detected newer upload does not automatically override an earlier instruction.

Users can edit extracted fields, reject a task, merge duplicates and delete an import. Changes to an existing confirmed deadline require another confirmation. Reminders will be tested with notification permission granted and denied, with the app closed, and after device restart.

Practical boundaries

Proposed pilot limits are 10 MB per image, 20 pages per PDF or DOCX, 10 minutes per audio file and 3 minutes per video. These are design limits pending service and device tests, not measured capabilities. The first release prioritises clear printed text and intelligible Mandarin audio. Unsupported, encrypted or damaged files receive an explicit error.

Class recordings and shared documents should be used with the relevant permission. The design keeps imports private by default. The planned interface explains cloud processing before upload and offers deletion of source material and extracted records. Any retention promise must match the selected provider and the implemented storage policy. Demonstrations use team created or authorised samples.

4 Marketing and business model

Our initial message is practical: share an assignment notice, check the extracted requirements and save a reminder. A short demonstration will show both a correct extraction and an ambiguous deadline so students can judge the review effort. No claim of guaranteed accuracy or official university endorsement will be used.

Channel	Pilot action and proposed owner	Measurement
Course cohort	Research lead requests permission from a group administrator and invites up to 30 students using a 30 second demonstration.	Invitations, sign ups and confirmed first tasks.
Student groups	Outreach lead invites up to 20 additional students through one relevant society or group leader.	Activation by source and interview participation.
Peer referrals	Product lead offers an optional invitation link after a successful task review.	Unique referred sign ups and returning users.

The 50 invitations are a combined pilot target. Activation means a participant imports a source and confirms at least one task. A returning user means an activated participant performs another meaningful task action within seven days. Channel attribution must avoid counting the same student twice.

Pilot budget and revenue hypothesis

The first trial is free. A later model could retain a small free allowance and charge for additional transcription or document processing. A willingness to pay question alone will not demonstrate paying demand. Institutional sales require a different buyer and approval process, so they are not an initial acquisition assumption.

Planning item	Illustrative allocation in CNY
AI processing and storage	100
Optional participant thank you payments	60
Other pilot costs and contingency	40
Total proposed cash ceiling	200

These amounts are a proposed spending cap, not vendor quotations or approved purchases. Student development labour and existing equipment are excluded. The team can run a zero incentive pilot and reduce processing volume if the budget is lower.

We will track variable cost per import and per activated user. For illustration only, a CNY 9 monthly price and CNY 3 variable cost would leave CNY 6 before fixed costs and acquisition. With CNY 120 monthly fixed costs, 20 paying users would cover those fixed costs. Neither the price, cost nor conversion is validated. Long recordings and videos could materially increase costs, so usage limits must follow actual metering.

Why a student might keep using it

Retention depends on repeated course requirements, low review effort and trust in source references. We will observe second imports and task corrections rather than treat downloads as proof of value. If manual entry is faster, the team will simplify the workflow or narrow the supported use case.

5 Validation and delivery plan

Before the first phase presentation

We plan to conduct 6 to 8 short interviews with consenting students. We will ask about their most recent assignment notice, how they recorded its deadline and whether a revision caused confusion. Participants will describe their current process using a non sensitive example before seeing the concept. We will record anonymous observations and counterexamples. No interview findings are claimed in this proposal.

A labelled storyboard will test whether students understand the proposed workflow. There is not enough time before October 21 to obtain seven day retention results, so those belong to the later prototype pilot.

Prototype evaluation

Measure	Method and proposed acceptance target
Extraction quality	Prepare 40 held out examples: 10 each for image, document, audio and short video. Two team members label the expected tasks and resolve differences. Report precision and recall by modality. Initial target: at least 90% for each overall.
Deadline reliability	Measure exact interpretation on examples with explicit dates and flagging on ambiguous or conflicting cases. Target: at least 95% exact match on explicit cases; zero silently invented deadlines in this small test set.
User effort	Six users complete comparable tasks manually and with the prototype in counterbalanced order. Measure elapsed time including review, corrections and errors. Target: median time at least 30% lower without increased critical errors.
Activation and return	Pilot targets: 12 of 20 sign ups confirm a first task; 6 of those 12 take another meaningful action within seven days. These are decision thresholds, not results.

Precision is correct extracted tasks divided by all extracted tasks. Recall is correct extracted tasks divided by all expected tasks. Report counts as well as percentages, and record unsupported formats separately. A small curated test does not establish reliability across all classroom conditions. Revise the scope if results miss the targets.

Phase one schedule

October 19: confirm team details and project scope, organise repository access and begin interviews. October 20: incorporate genuine observations, finalise the business plan and README, upload the materials and rehearse. Treat October 20 evening as the internal upload deadline because the assignment says "before October 21st". October 21: check materials and present at 18:30 in Laboratory 110, subject to any updated teacher notice [5].

The confirmed four person team is led by 何嘉俊 and includes 王舜祺, 陈实 and 李文豪. Proposed roles are coordination and repository management, product and AI integration, user research and market analysis, and interface concepts and presentation respectively. Role allocation is subject to team agreement and skills.
